# Background

## Strategic Environmental Research and Development Program (SERDP)

### Project Context

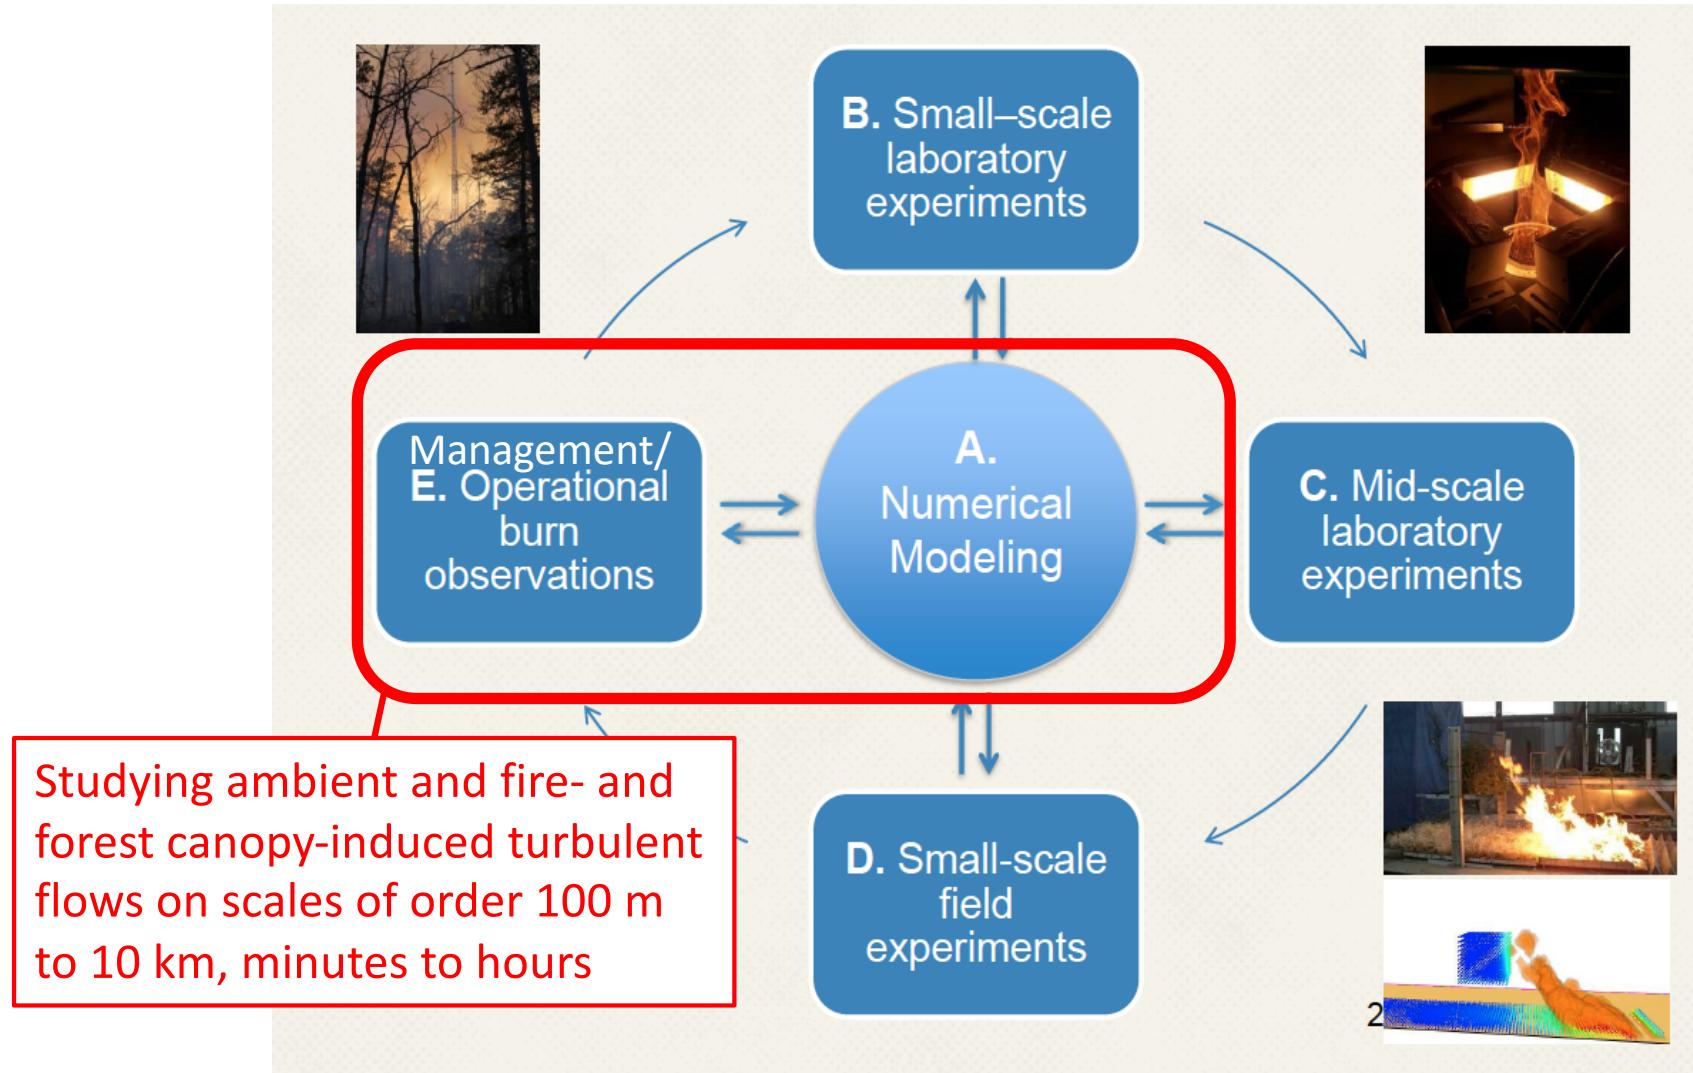

#### IMPROVED UNDERSTANDING OF WILDLAND FIRE COMBUSTION PROCESSES FOR DEPARTMENT OF DEFENSE MANAGED ECOSYSTEMS

Low-intensity, backing fires:  
Broad range of relevant scales (order of sub-millimeter to 10 km)

- Given the prevalence of the use of prescribed fire by Department of Defense (DoD) managers to mimic historical, low-intensity surface fires, a primary focus is improved understanding of the processes involved in **fine-fuel heat exchange, ignition, and fire spread** and how they may be affected by **fuel condition**.
- Outcomes of proposed research should be developed in a manner that enables them to be incorporated into fire behavior models useful for predicting ecological effects and emissions responses.

# Background

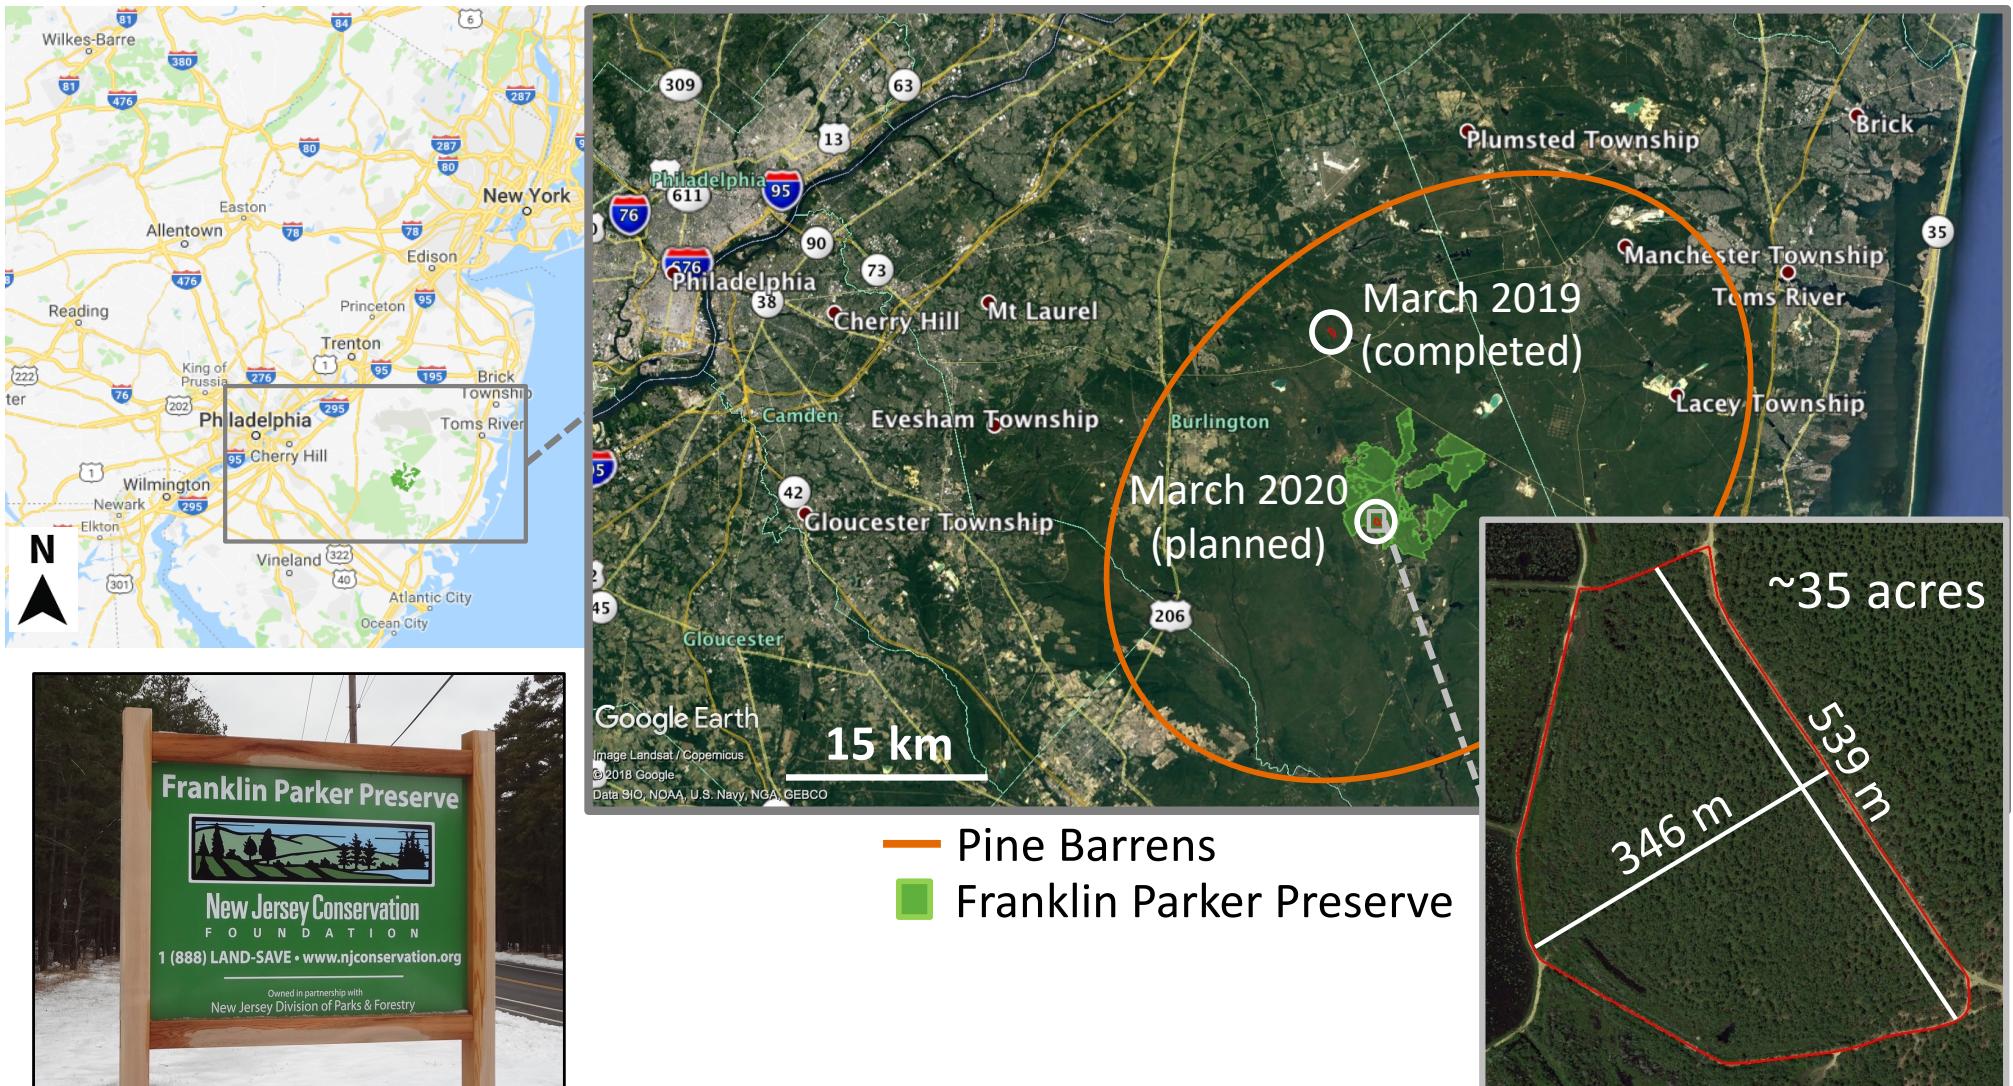

*Adapted from Nick Skowronski's North Atlantic Fire Science Exchange webinar [2 May 2018]*

# Background

Model studies of ambient and fire- and forest canopy-induced turbulence can

- Lead to improvements in prediction of smoke dispersion, tree mortality, fire behavior, etc.
- Help answer questions that field campaigns alone are unable to address (more degrees of freedom)
- • Provide guidance for instrument placement prior to field campaigns

# 2020 SERDP management-scale burn site: Franklin Parker Preserve, NJ

# Objective

Use high-resolution atmospheric simulations to help guide the deployment of a monitoring network for a management-scale prescribed fire experiment. Identify areas of burn block with:

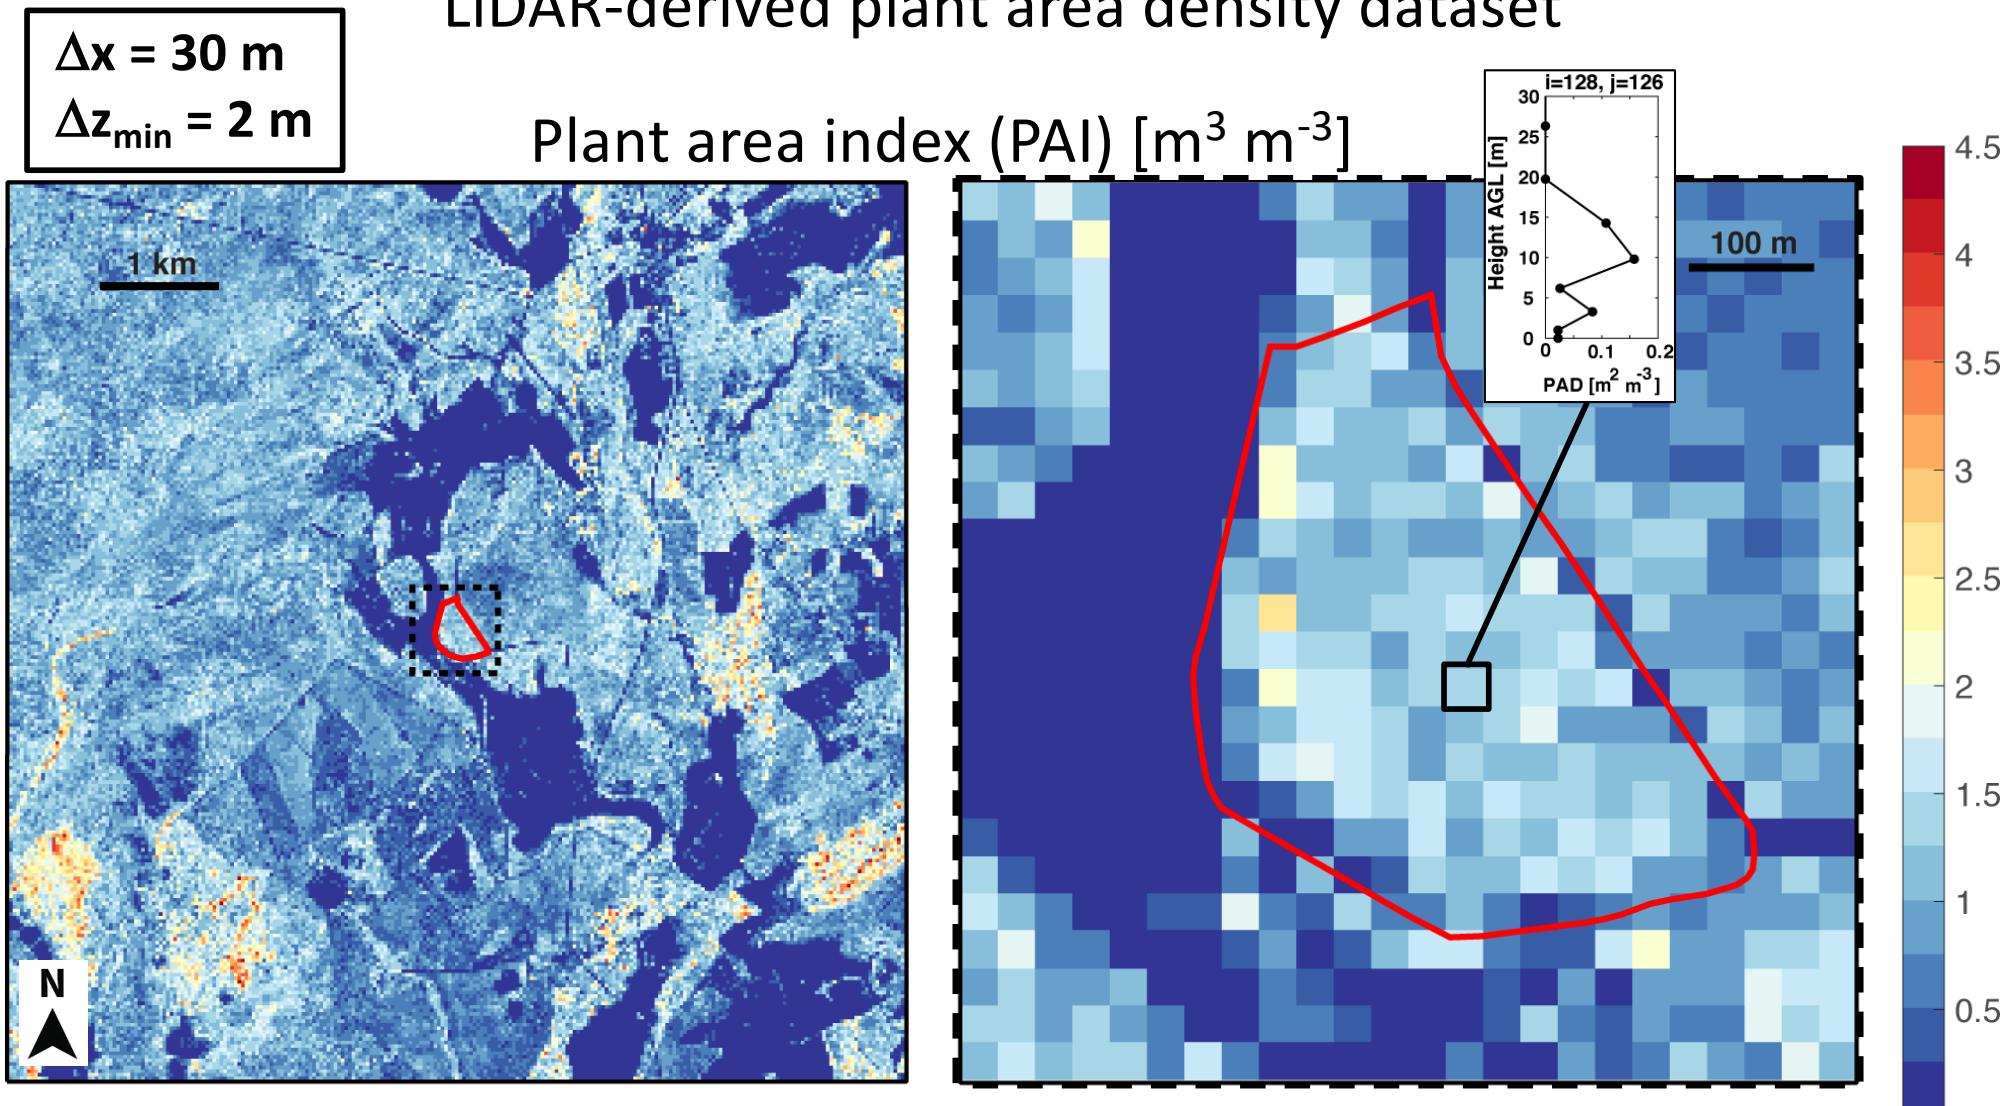

- Stronger gradients in simulated variables
- Less sensitivity of simulated variables to changes in fire and background conditions
- Simulated phenomena of interest (e.g., vortices)  
**\*\*The preliminary results shown here  
are intended as a proof-of-concept \*\***

# ARPS-CANOPY overview

- Core: Advanced Regional Prediction System (ARPS) (Xue et al. 2000,2001)
  - Atmospheric model developed for weather prediction at multiple scales
- Canopy sub-model (Kiefer et al. 2013):
  - Explicitly accounts for canopy drag, enhancement of turbulence dissipation, and wake turbulence production
  - Parameterizes heating/cooling of vegetation elements, shading of ground surface, and canopy-atmosphere moisture exchange
  - Canopy is represented by a plant area density profile
- Fire is parameterized as an area of enhanced surface vertical heat flux (one-way coupled to atmosphere)

# Model setup and experiment design

LiDAR-derived plant area density dataset

# Model setup and experiment design

Backing fire representation

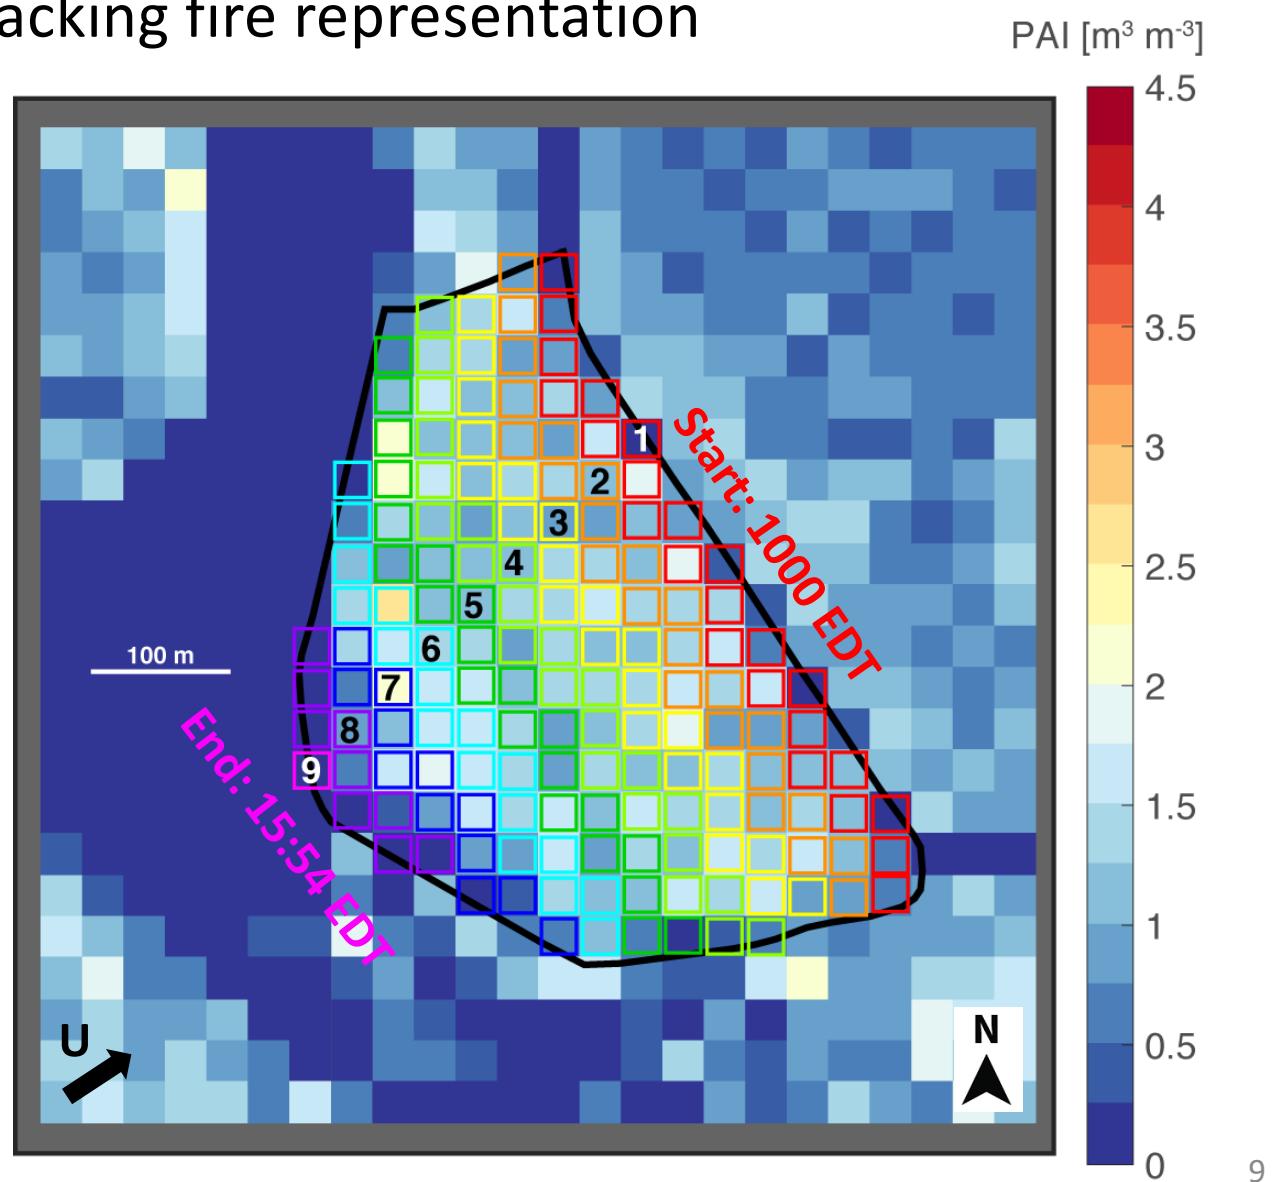

**1 m min<sup>-1</sup>  
spread rate  
(steady-state)**

---

**5 hr 54 min burn  
period**

---

**Surface heat flux  
varied four ways:  
0, 5, 10, 25 kW m<sup>-2</sup>**

# Model setup and experiment design

## Model initialization

- Model initialized with idealized wind and temperature profiles
- Constrained by location (central NJ), time of year (March), time of day (0800 EDT), and burn block details (shape, backing fire mode)

<b>WS<sub>1-m</sub></b>	<b>WS<sub>500-m</sub></b>	<b>WD<sub>ALL</sub></b>	<b>T<sub>1-m</sub></b>	<b>RH<sub>1-m</sub></b>
1.4 ms <sup>-1</sup> (3.1 mph)	2.5 ms <sup>-1</sup> (5.6 mph)	236.5° (WSW)	1.3 °C (34.3°F)	62.2 %

- Surface energy budget appropriate for mid-March
- Flat terrain

# Results

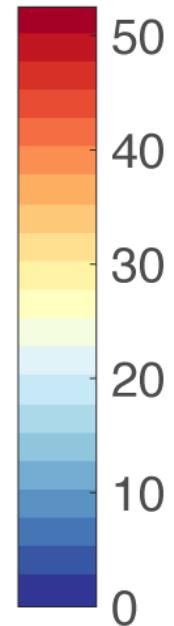

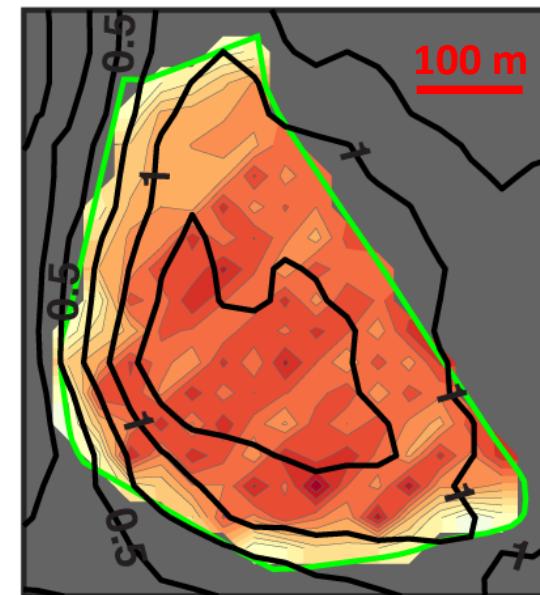

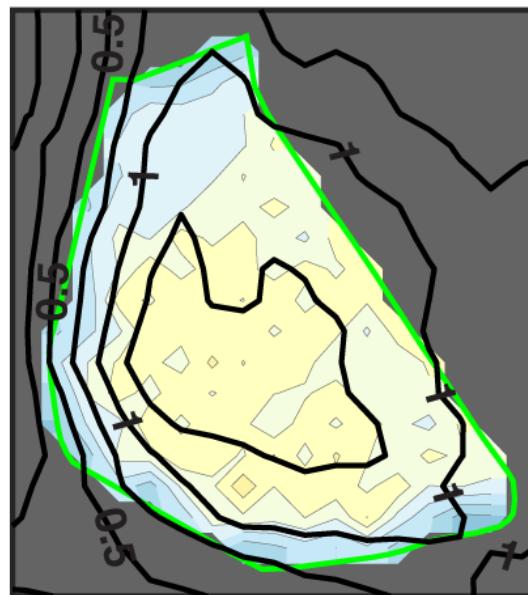

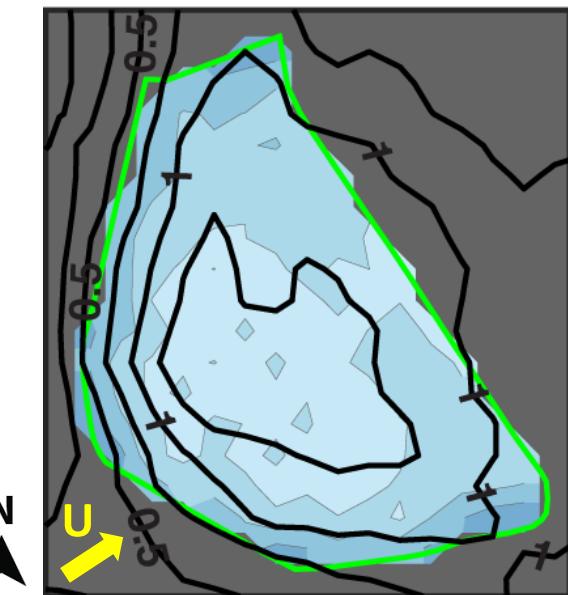

1 m AGL Temperature [°C]

1-min mean  
Burn period 90<sup>th</sup> percentile

$H_f = 5 \text{ kW m}^{-2}$

$H_f = 10 \text{ kW m}^{-2}$

$H_f = 25 \text{ kW m}^{-2}$

- Temperature gradient strongest near southern and western perimeter
  - Consistent across cases
- Interior heterogeneity increases with increasing heat flux

# Results

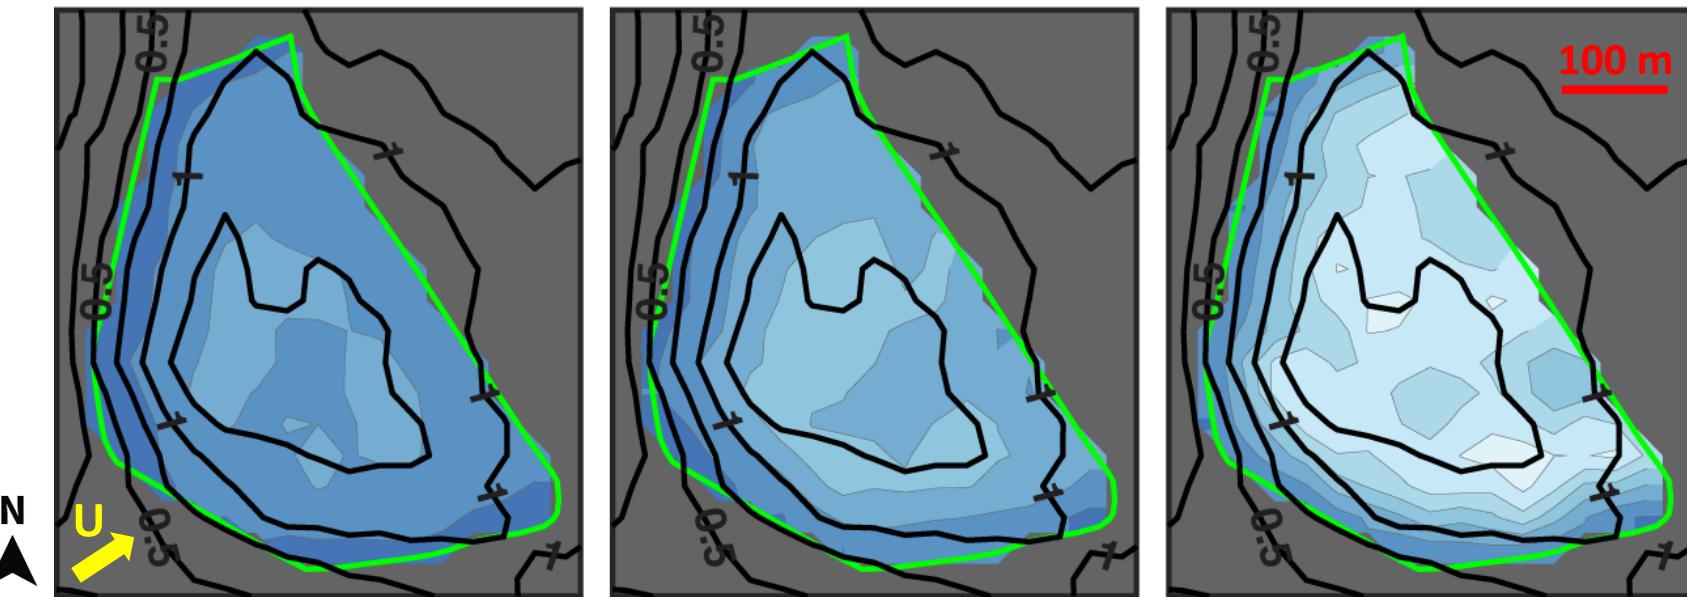

9.8 m AGL Temperature [°C]

1-min mean  
Burn period 90<sup>th</sup> percentile

$H_f = 5 \text{ kW m}^{-2}$

$H_f = 10 \text{ kW m}^{-2}$

$H_f = 25 \text{ kW m}^{-2}$

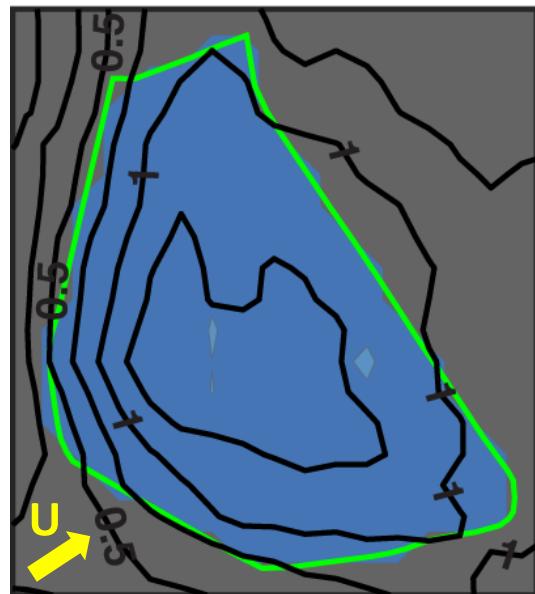

- Denser vegetation → higher temperatures
  - Consistent across cases

# Results

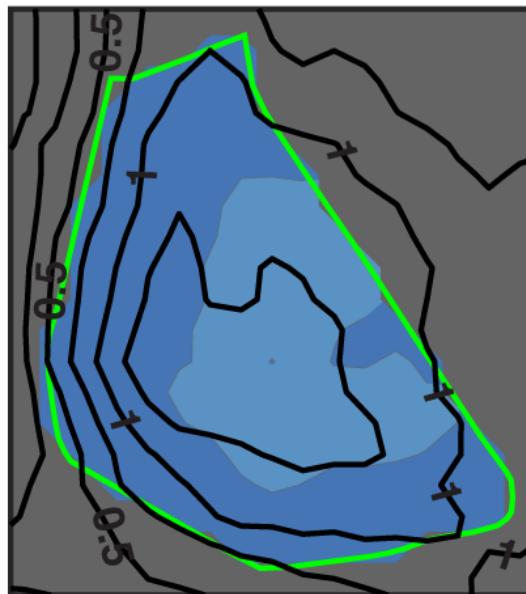

26.3 m AGL Temperature [ $^{\circ}\text{C}$ ]

1-min mean  
Burn period 90<sup>th</sup> percentile

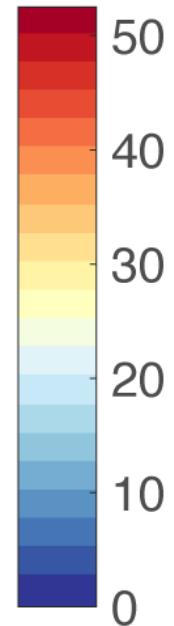

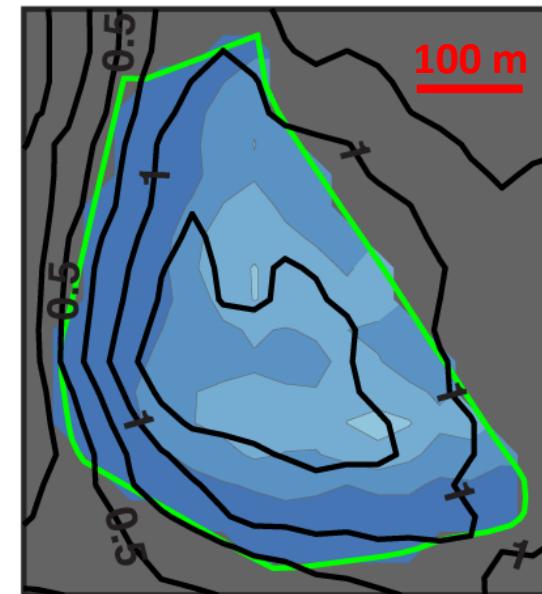

$H_f = 5 \text{ kW m}^{-2}$

$H_f = 10 \text{ kW m}^{-2}$

$H_f = 25 \text{ kW m}^{-2}$

- Denser vegetation  $\rightarrow$  higher temperatures
  - Consistent across cases
  - Pattern more homogeneous than at other levels

# Results

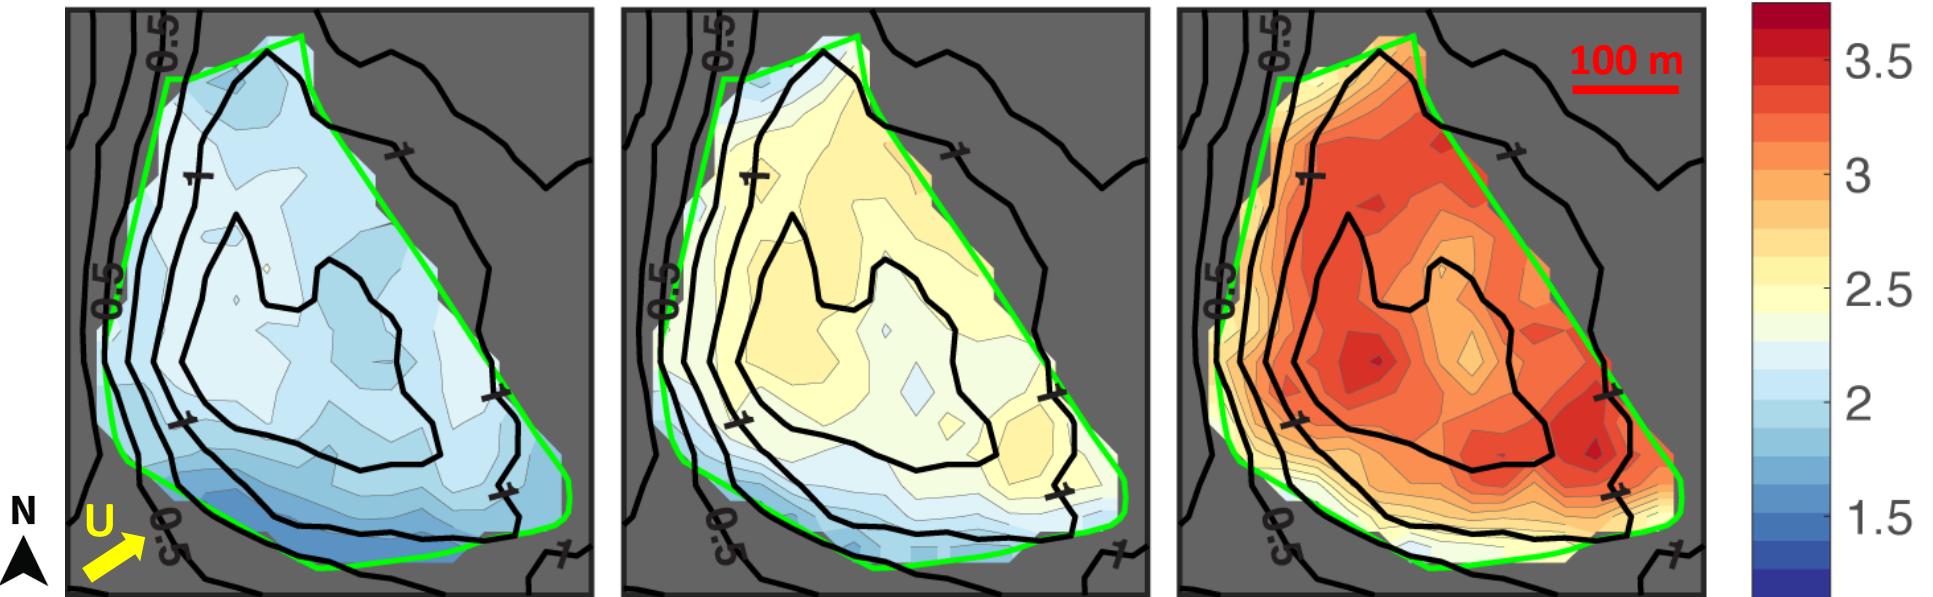

1 m AGL Wind speed [ $\text{m s}^{-1}$ ]

1-min mean  
Burn period 90<sup>th</sup> percentile

$H_f = 5 \text{ kW m}^{-2}$

$H_f = 10 \text{ kW m}^{-2}$

$H_f = 25 \text{ kW m}^{-2}$

- Wind speed gradient strongest near southern perimeter
  - Consistent across cases
- Spatial pattern of wind speed consistent across cases

# Results

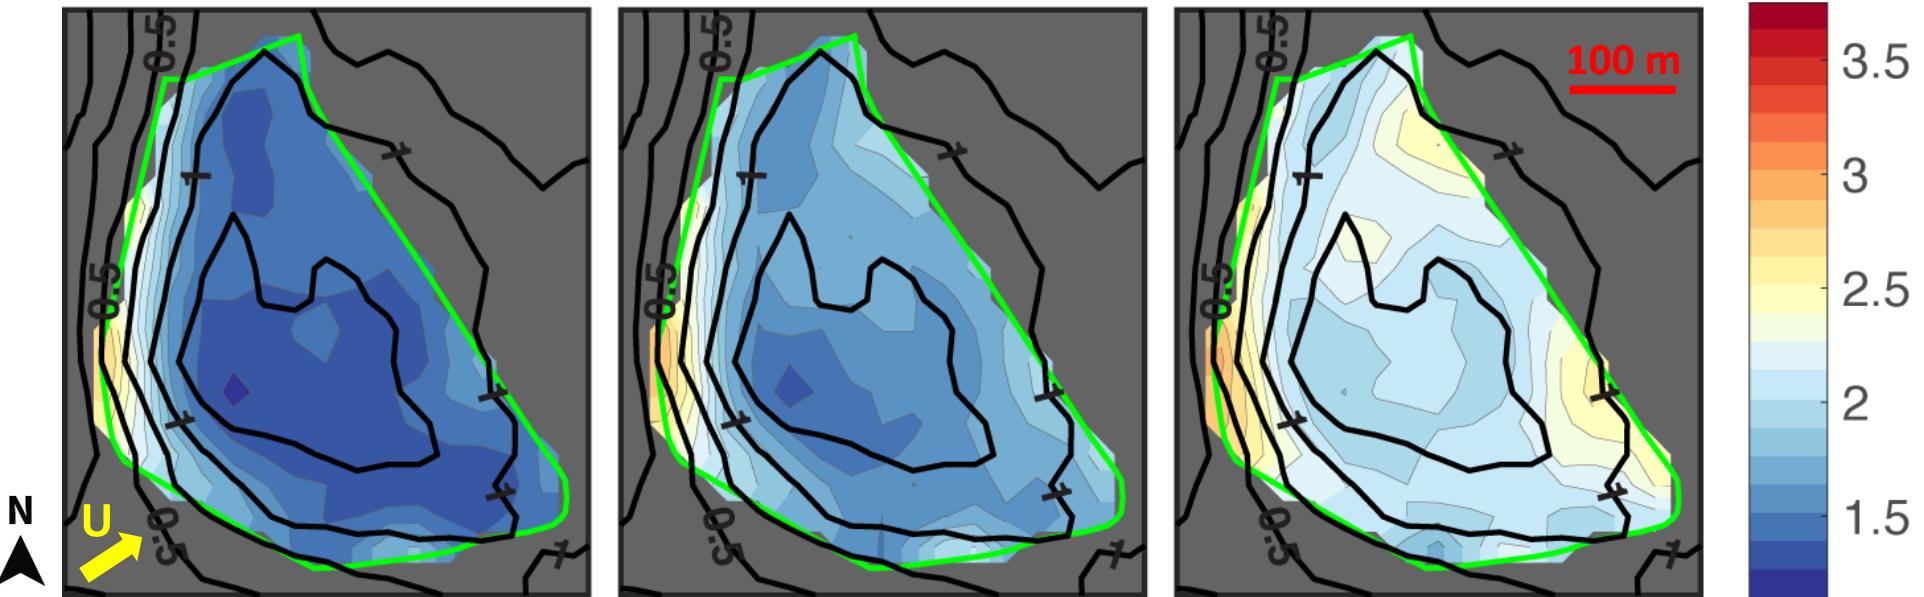

9.8 m AGL Wind speed [ $\text{m s}^{-1}$ ]

1-min mean  
Burn period 90<sup>th</sup> percentile

$H_f = 5 \text{ kW m}^{-2}$

$H_f = 10 \text{ kW m}^{-2}$

$H_f = 25 \text{ kW m}^{-2}$

- Wind speed gradient strongest near western perimeter
  - Consistent across cases
- Magnitude of upwind gradient weakens with increasing heat flux

# Results

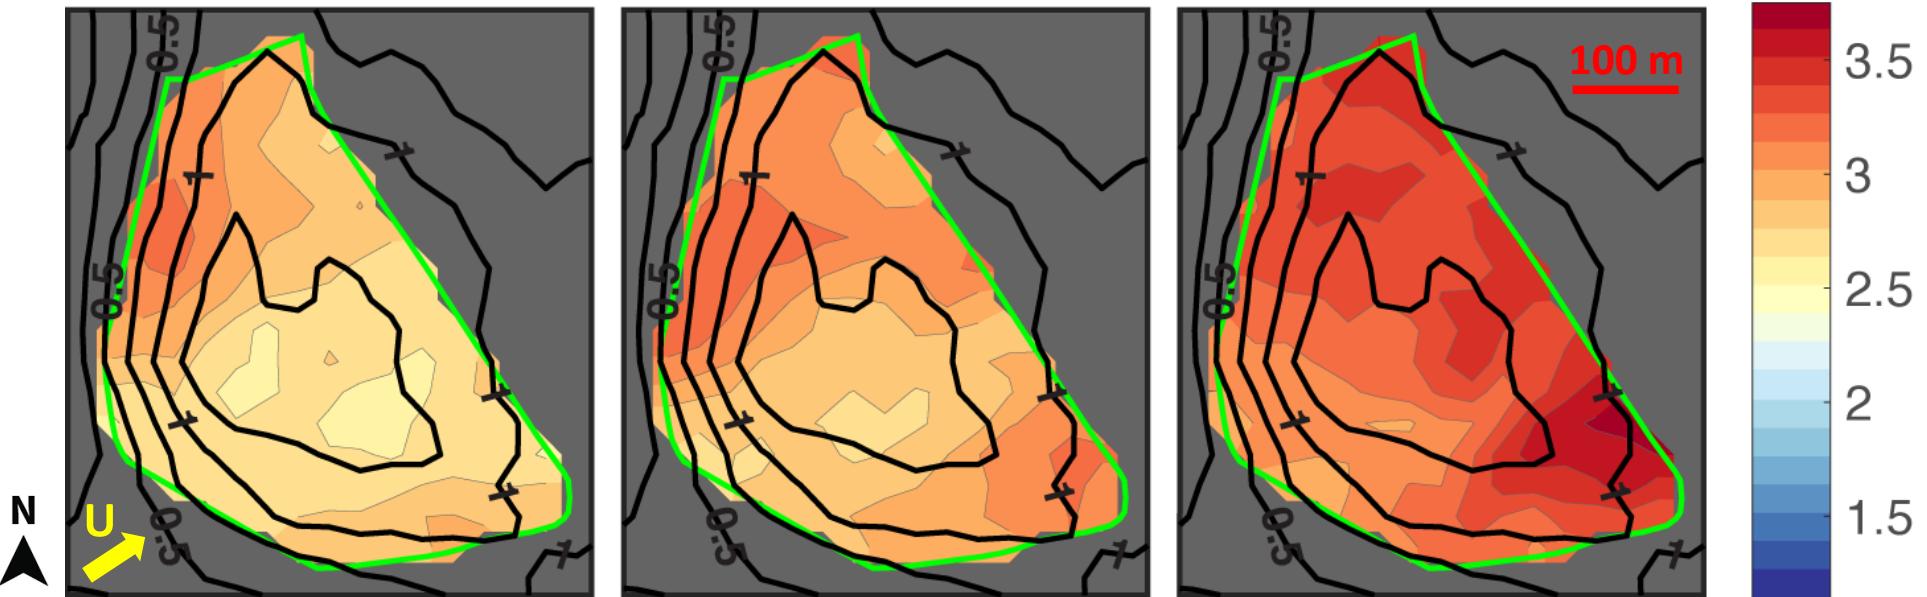

26.3 m AGL Wind speed [ $\text{m s}^{-1}$ ]

1-min mean  
Burn period 90<sup>th</sup> percentile

$H_f = 5 \text{ kW m}^{-2}$

$H_f = 10 \text{ kW m}^{-2}$

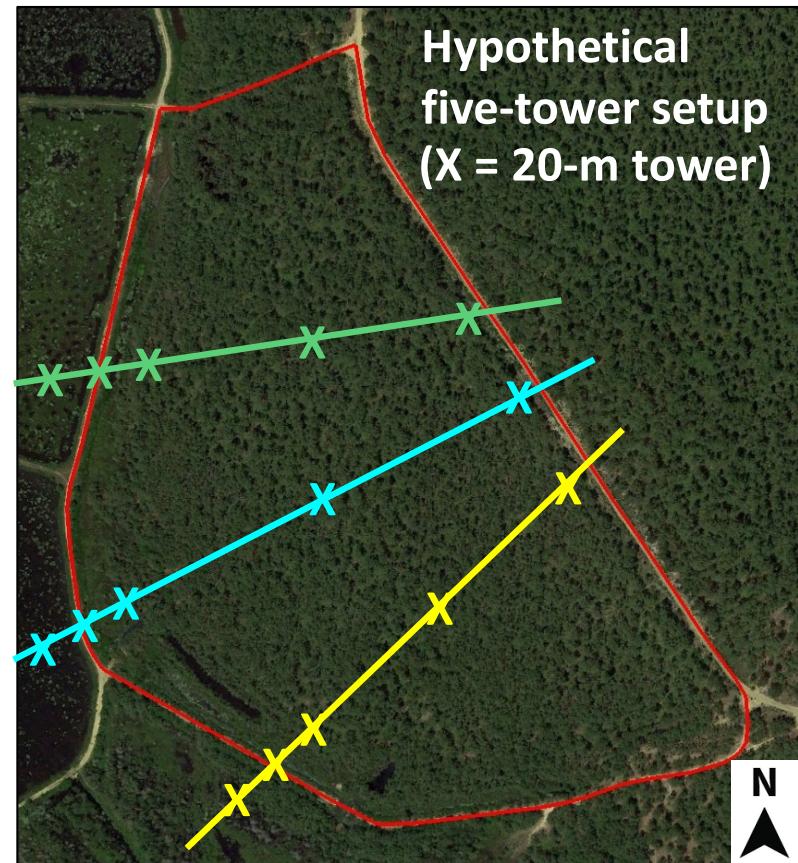

$H_f = 25 \text{ kW m}^{-2}$

- Spatial pattern inconsistent across cases
- Pattern noticeably different at all three levels

# Summary & Conclusions

- Modeling framework developed here shows promise for informing instrumentation deployment strategy
  - Preliminary results shown here suggest one or more linear arrangements, with clustering where simulated gradients were overall strongest

# Summary & Conclusions

- Modeling framework developed here shows promise for informing instrumentation deployment strategy
- Deployment recommendations may depend on variables of greatest interest: e.g., **temperature**, **wind speed**, turbulent quantities (turbulent kinetic energy, sweeps/ejections), radiation
- Actual deployment strategy subject to late adjustments based on weather forecasts, and above all, on-the-ground expertise

# Next Steps

- Perform ARPS-CANOPY simulations of 13 March 2019 prescribed fire in Silas Little Exp. Forest, NJ
- Perform additional sensitivity simulations of Franklin Parker Preserve fire (planned: 2020):
  - Vary background weather conditions (wind, stability)
- Synthesize findings of pre-burn simulations to provide guidance for 2020 field deployment
